

Hosting, database and Zoho — the short version

1 Hosting — Vercel

One deployment serves everything a person looks at: the marketing site, all 12 screens, all three portals, the fan QR page. Push to GitHub, Vercel builds it, it's live.

Two things sit outside it on purpose — the **background worker on Railway**, because Vercel kills long-running requests and a 12-page PDF is exactly that; and **files on Cloudflare R2**, because athlete video doesn't belong in a web host.

2 Database — one Postgres, run by Neon

Every record in the product, plus the job queue and the audit log.

Notably **not** in it: passwords (Clerk), files (R2), invoices (Zoho), bank details (nowhere — §26 forbids it), and tax IDs, which need a restricted store you should decide on before athlete one.

3 Zoho — the sales system, not the platform

One sentence settles most future arguments: **Zoho knows who you're selling to and whether they've paid; SponsorX knows what was promised, who's delivering it and whether it worked.**

Three exchanges cross between them, all through the worker, all queued. If Zoho goes down, sponsors still browse, athletes still accept orders, fans still redeem — syncs just wait.
